Abstract—The field of signal or image processing naturally deals with the image de-noising. The image may be corrupted by a noise and/or poor illumination and/or high temperature, and/or transmission. The ability of capturing the energy of signal provides us the better solution towards de-noising of a natural images corrupted by Gaussian noise using multi-wavelet techniques. Multi-wavelet can gratify with symmetry and asymmetry which are very imperative characteristics in signal processing. The image will be highly de-noised if and only if the degree of the noise is lesser. Normally, its energy is dispersed over low frequency band while both its noise and details are dispersed over high frequency band. Corresponding hard threshold used in various scale high frequency sub-bands. In this paper proposed to indicate the aptness of various wavelets and multi-wavelet based and a size of different neighborhood on the performance of image de-noising algorithm in terms of PSNR value. Finally it compares wavelet and multi-wavelet techniques and produces best de-noised image using multi-wavelet technique based on the performance of image de-noising algorithm in terms of PSNR Values.

Keywords—Gaussian noise, PSNR Values, multi-wavelet
I. INTRODUCTION

This paper investigates the suitability of different wavelet bases and the size of different neighborhood [1][4][5] on the performance of image de-noising algorithms in terms of PSNR. Over the past decade, wavelet transforms have received a lot of attention from researchers in many different areas. Both discrete and continuous wavelet transforms have shown great promise in such diverse fields as image compression, image de-noising, signal processing, computer graphics, and pattern recognition to name only a few. In de-noising, single orthogonal wavelets with a single-mother wavelet function have played an important role. De-noising of natural images corrupted by Gaussian noise using wavelet techniques is very effective because of its ability to capture the energy of a signal in few energy transform values. Crudely, it states that the wavelet transform yields a large number of small coefficients and a small number of large coefficients.

The problem of Image de-noising can be summarized as follows. Let A (i,j) be the noise-free image and B(i, j) the image corrupted with independent Gaussian noise [10] Z (i, j)

\[ B(i, j) = A(i, j) + \sigma Z(i, j) \]  

(1)

Where Z (i, j) has normal distribution N(0, 1). The problem is to estimate the desired signal as accurately as possible according to some criteria. In the wavelet domain, if an orthogonal wavelet transform is used, the problem can be formulated as

\[ Y(i, j) = W(i, j) + N(i, j) \]  

(2)

where Y(i,j) is noisy wavelet coefficient; W(i,j) is true coefficient and N(i,j) noise, which is independent Gaussian.

In multi-wavelet [2] aspects, the symmetry and dissymmetry of the wavelet is rather important in signal processing. But single-wavelets with orthogonal intersection and compact-supporting are not symmetric except Harr. Recently, research on multi-wavelet is an active orientation. As multi-wavelet can satisfy both symmetry and asymmetry which are very important characters in signal processing. Multi-wavelet is commonly used in image compression, image de-noising, digital watermark and other signal processing field, so it is especially appropriate to processing complex images.

There are r compact-supporting scaling functions \( \theta = (\theta_1, \theta_2, \ldots, \theta_r) \) and they are inter-orthogonal with the wavelet functions \( \psi = (\psi_1, \psi_2, \ldots, \psi_r) \) \( \theta_l(t) \) \( l=1, 2, \ldots, r \). \( H_b, G_k \) is the \( N \times N \) matrix finite response filters with orthogonal basis, and then the following specific equations can be obtained:

\[ \theta(t) = \sum_{k \in \mathbb{Z}} h_k \theta(2t - k) \]  

(3)

\[ \psi(t) = \sum_{k \in \mathbb{Z}} h_k \theta(2t - k) \]  

(4)

II. MULTI-WAVELET TRANSFORM

The Multi-Wavelet[3][6][12] Transform of image signals produces a non-redundant image representation, which provides better spatial and spectral localization of image formation, compared with other multi scale representations such as Gaussian and Laplacian pyramid. Recently, Multi-Wavelet Transform has attracted more and more interest in image de-noising.

Multi-wavelet iterates on the low-frequency components generated by the first decomposition. After scalar wavelet decomposition, the low-frequency components have only one sub-band, but after multi-wavelet decomposition, the low-frequency components have four small sub-bands, one low-pass sub band and three band-pass sub bands. The next iteration continued to decompose the low frequency components \( L = \{L_1L_1, L_1L_2, L_2L_2, L_2L_1\} \). In this situation, a structure of \( 5(4^*J+1) \) sub bands can be generated after \( J \) times decomposition, as shown in figure 1. The hierarchical relationship between every sub-band is shown in figure 2. Similar to single-wavelet, multi-wavelet can be decomposed to 3 to 5 layers.
The Gaussian noise will nearby be averaged out in low frequency Wavelet coefficients. Therefore only the Multi-Wavelet coefficients in the high frequency level need to hard be threshold [7].

\[ T = \sigma \sqrt{2 \log_2 n} \]

This method performs well under a number of applications because wavelet transform has the compaction property of having only a small number of large coefficients. All the rest wavelet coefficients are very small. This algorithm offers the advantages of smoothness and adaptation. However, it exhibits visual artifacts.

**Method B Neighshrink**

Let \( d(i,j) \) denote the wavelet[14] coefficients of interest and \( B(i,j) \) is a neighborhood window around \( d(i,j) \). Also let \( S^2 = \sum d^2(i, j) \) over the window \( B(i, j) \). Then the wavelet coefficient to be threshold is shrinked according to the formulae,

\[ d(i,j) = d(i,j) \times B(i,j) \]

where the shrinkage[3] factor can be defined as

\[ B(i,j) = \|1 - \frac{T^2}{S^2(i,j)}\| , \text{and this formulae yields positive result.} \]

**Method C Modineighshrink**

During experimentation, it was seen that when the noise content was high, the reconstructed image using Neigh shrink contained mat like aberrations. These aberrations could be removed by wiener filtering the reconstructed image at the last stage of IDWT [13]. The cost of additional filtering was slight reduction in sharpness of the reconstructed image. However, there was a slight improvement in the PSNR of the reconstructed image using wiener filtering. The de-noised image using Neigh shrink sometimes unacceptably blurred and lost some details. The reason
could be the suppression of too many detail wavelet coefficients. This problem will be avoided by reducing the value of threshold itself. So, the shrinkage [3] factor is given by

\[ B(i,j) = \| 1 - (3/4)^2 S^2 (i,j) \| \]

IV. HARD THRESHOLD FOR MULTIWAVELET
The key of wavelet threshold in image de-noising is how to evaluate the coefficients. Although the methods of hard and soft threshold [1] are used widely in practice, there are many faults in their nature. Hard threshold is to keep datum greater than the threshold, and all data less than the threshold are put to zero, the formula is as following:

\[
A^{'}_{j,k} = \begin{cases} 
A_{j,k} & \text{if } |A_{j,k}| \geq \sigma \\
0 & \text{if } |A_{j,k}| < \sigma 
\end{cases}
\]

Where \( \sigma \) is threshold and \( A_{j,k} \) the wavelet coefficients.

In hard threshold, \( A_{j,k} \) which are discontinuous at \( \sigma \) will bring some concussions and large mean-square deviation to the reconstructed signal.

V. DE-NOISING PROCESS FOR MULTI-WAVELET

If the noised image is

\[ I(i,j) = X(i,j) + n(i,j) \quad i,j=1,2,\ldots,N \quad (3) \]

Where \( n(i,j) \) is white Gaussian noise whose mean value is zero, \( \sigma \) is its variance, and \( X(i,j) \) the original signal.

The problem of de-noising can be thought as how to recover \( X(i,j) \) from \( I(i,j) \). Transform the formula (3) with multiwavelet, formula (4) is obtained

\[ W_1(i,j) = W_x(i,j) + W_n(i,j) \quad (4) \]

It is known from multi-wavelet transformation that, the multi-wavelet transformation of Gaussian noise is also Gaussian distributed, there are components at different scales, but energy distributes evenly in high frequency area, and the specific signal of the image has projecting section in every high frequency components. So image de-noising can be performed in high frequency area of multi-wavelet transformation. The above said methods are evaluated using the quality measure Peak Signal to Noise ratio which is calculated using the formulae,

\[ \text{PSNR} = 10 \log_{10} \left( \frac{255}{2} \right) \frac{\text{MSE}}{} \text{ (db)} \]

Where MSE is the mean squared error between the original image and the reconstructed de-noised image. It is used to evaluate the different de-noising scheme like Wiener filter, Visushrink, Neigh shrink [11], ModifiedNeighshrink and multi-wavelet.

VI. PROPOSED ARCHITECTURE

In this proposed approach of denoising the first step will cover preprocessing for the input image, we are using Row preprocessing method. After preprocessing we will transform the image into the multiwavelet as domain using an orthogonal periodic multiwavelet transform. Now the thresholds will be calculated by using the proposed method.
Perform the inverse multiwavelet transform to obtain the reconstruction information then perform post-processing the reconstruction information to get the denoised image.

![Proposed Architecture Diagram](image)

Fig. 3 Proposed Architecture

PSNR value: The image mean square error and peak value signal-to-noise ratio were applied to estimate the de-noising effect of the image. Peak Signal to Noise ratio (PSNR) which is calculated using the formula,

$$\text{PSNR} = 10 \log_{10} \frac{255^2}{\text{MSE}} \text{ (db)}$$

where MSE is the mean squared error between the original image and the reconstructed de-noised image. It is used to evaluate the different denoising scheme like Wiener filter, Neighshrink etc.

VIII. CONCLUSION

In this paper, the image de-noising using Discrete Wavelet Transform and Multi-Wavelet transform is analyzed the experiments were conducted to study the suitability of different wavelet and multi-wavelet bases and also different window sizes. Experimental Results also show that multi-wavelet with hard threshold gives better result than Modified Neigh shrink, Neigh shrink, Weiner filter and Visushrink.

Multiwavelets are a new addition to the body of wavelet theory. Realizable as matrix-valued filter banks leading to wavelet bases, multiwavelets offer simultaneous orthogonality, symmetry, and short support, this is not possible with scalar 2-channel wavelet systems. After reviewing this recently developed theory, we examine the use of multiwavelets in a filter bank setting for discrete-time signal and image processing. Multiwavelets differ from scalar wavelet systems in requiring two or more input streams to the multiwavelet filter bank. After reviewing the recent notion of multiwavelets (matrix-valued wavelet systems), we have examined the use of multiwavelets in a filter bank setting for discrete-time signal processing.
