Abstract: The evolution of Cloud computing makes the major changes in computing world as with the assistance of basic cloud computing service models like SaaS, PaaS, and IaaS an organization achieves their business goal with minimum effort as compared to traditional computing environment. On the other hand security of the data in the cloud database server is the key area of concern in the acceptance of cloud. It requires a very high degree of privacy and authentication. To protect the data in cloud database server cryptography is one of the important methods. Cryptography provides various symmetric and asymmetric algorithms to secure the data. This paper presents the symmetric cryptographic algorithm named as AES (Advanced Encryption Standard). It is based on several substitutions, permutation and transformation.

1. INTRODUCTION

Cloud Computing is a set of IT Services that are provided to a customer over a network and these services are delivered by third party provider who owns the infrastructure. It is often provided "as a service" over the Internet, typically in the

form of infrastructure as a service (IaaS), platform as a service (PaaS) and software as a service (SaaS). Cloud computing is the broader concept of infrastructure convergence. This type of data centre environment allows enterprises to get their applications up and running faster, with easier manageability, and less maintenance to meet business demands. For example, we can manage and store all smartphones or tablets apps at one location i.e. cloud. So we do not require any memory space at our end. This also gives the security of data and applications in case device is damaged or lost.

As the central data storage is the key facility of the cloud computing it is of prominent importance to provide the security. The art and science of concealing the messages to introduce secrecy in information security is recognized as cryptography. Security goals of data cover three points namely: Availability, Confidentiality, and Integrity. Cryptography, in modern days is considered grouping of three types of algorithms. They are:

Symmetric-key algorithms

Asymmetric-key algorithms

Hash functions

Symmetric algorithms use the same key for encryption and decryption. This is termed as secret key. With the same key messages are encrypted by the sender and decrypted by the receiver. It contains algorithms like Data Encryption Standard (DES), Advanced Encryption Standard (AES), Ron's Code (RCn), and Triple DES, Blowfish etc.

Asymmetric algorithms use different keys. One key (public) is used for encryption and other (private key) is used for decryption. This is named as public key. Public key is known to public and private key is known to the user. It comprises various algorithms like Rivest, Shamir, & Adleman (RSA), Digital Signature Algorithm (DSA), Elliptic Curve(EC), Diffi-Hillman(DH), El Gamal etc.

The Hash functions use a mathematical transformation to irreversibly "encrypt" information. It contains algorithms like Message Digest, Secure Hash Algorithm.

We choose symmetric cryptosystem as solution as it has the speed and computational efficiency to handle encryption of large volumes of data. In symmetric cryptosystems, the longer the key length, the stronger the encryption.

AES is most frequently used encryption algorithm today this algorithm is based on several substitutions, permutations and linear transformations, each executed on

data blocks of 16 byte. As of today, no practicable attack against AES exists. Therefore, AES remains the preferred encryption standard for governments, banks and high security systems around the world.

2. LITERATURE REVIEW

In [1], it is proposed a simple data protection model where data is encrypted using Advanced Encryption Standard (AES) before it is launched in the cloud, thus ensuring data confidentiality and security. In [4], a privacy-preserving public auditing system for data storage security in cloud computing is intended, although the computational time is increased but the privacy is preserved where data is stored in the cloud by using the most prominent algorithm AES.

In [8], AES data encryption is more scientifically capable and graceful cryptographic algorithm, but its main force rests in the key length. The time necessary to break an encryption algorithm is straight related to the length of the key used to secure the communication. AES allows choosing a various type of bits like 128-bit, 192-bit or 256-bit key, making it exponentially stronger than the 56-bit key of DES.

In [3], it is described a new architecture for security of data storage in multicloud. Two mechanisms-data encryption and file splitting are used. When user uploads a file, it is encrypted using AES encryption algorithm. Then that encrypted file is divided into equal parts according to the number of clouds and stored into multicloud. This proposed system enhances the data security in multicloud.

In [12], Based on the text files used and the experimental result it was concluded that AES Algorithm consumes least encryption and RSA consume longest encryption time. They also observed that Decryption of AES algorithm is better than other algorithms. From the simulation result, they evaluated that AES algorithm is much better than DES and RSA algorithm.

3. AES ALGORITHM

AES acronym of Advanced Encryption Standard is a symmetric encryption algorithm. The algorithm was developed by two Belgian cryptographers Joan Daemen and Vincent Rijmen. It is useful when we want to encrypt a confidential text into a decryptable format, for example when we need to send sensitive data in e-mail. The decryption of the encrypted text is possible only if we know the right password.

AES is an iterative rather than Feistel cipher. It is based on ‘substitution–permutation network’. It comprises of a series of linked operations, some of which involve replacing inputs by specific outputs (substitutions) and others involve shuffling bits around (permutations).

A.
The First Step

- AddRoundKey

B.

The Following Four Functions Are Periodically Repeated

- SubByte
- ShiftRow
- MixColumn
- AddRoundKey

C.

Final Step

- SubByte
- ShiftRow
- AddRoundKey

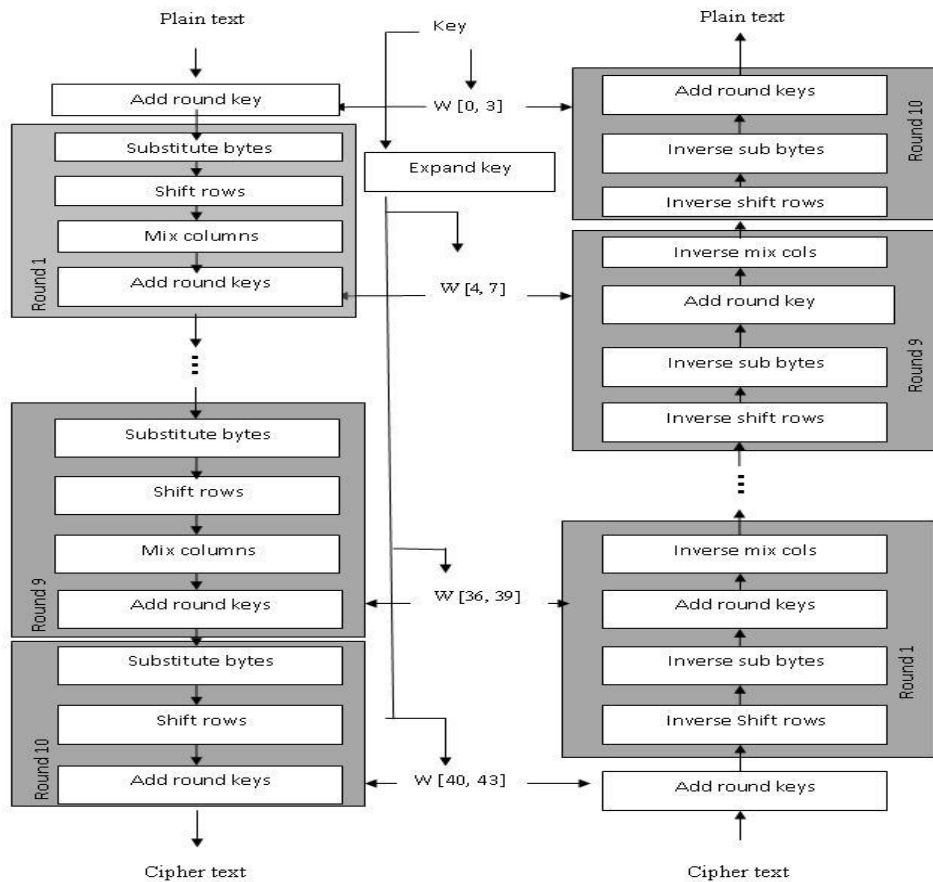

Fig. 1: Encryption and decryption in AES

4. CONCLUSION

According to a report, “Worldwide and Regional Public IT Cloud Services 2012-2016 Forecast” released by IDC, cloud services will see as much as 41% growth from 2013 to 2016. Spending on IT cloud services worldwide will edge toward \$100 billion by 2016 [13]. And in all this cloud growth, security will play a key role. AES encryption is the fastest method that has the flexibility and scalability and it is easily implemented. On the other hand, the required memory for AES algorithm is less than the Blowfish algorithm. AES algorithm has a very high security level because the 128, 192 or 256-bit key are used in this algorithm. It shows resistance against a variety of attacks such as square attack, key attack, key recovery attack and differential attack. Therefore, AES algorithm is a highly secure encryption method. Data can also protect against future attacks such as smash attacks. AES encryption algorithm has minimal storage space and high performance without any weaknesses and limitations while other symmetric algorithms have some weaknesses and differences in performance and storage space.
